Reflective Non-Exhaustion:

Certification, Realization, and the Summit Program

Nova Spivack

2026

Abstract

This short paper states the summit-level *reflective non-exhaustion* thesis in clear scope: canonical certification does not exhaust realization when comparison is tracked on the right carriers. We distinguish the claim from Gödel–style barrier theorems, from generic dependent-type proof relevance, and from informal slogans about "consciousness" or AGI. Routes C/A/B/D label how the thesis is supported internally, in applications, and in computability. For the map of manuscripts and discharges, see [5].

Keywords: reflective non-exhaustion, certification, realization, incompleteness, formal verification, Infinity Compression

1 Reflective Non-Exhaustion (summit statement)

Thesis. In structured reflective settings, a principal certified invariant at a bare carrier can coexist with nontrivial realization data above that carrier: the forgetful comparison map is sound but need not be injective, and multiplicity can be organized in fibers with explicit obstructions to trivializing lifts.
The Lean artifact instantiates this thesis with named definitions and theorems; the flagship paper [1] is the internal mathematical origin.

2 Broad structural class

The class of phenomena is not tied to a single domain: collapse/refinement/fiber appears in the internal library [1], in twelve external benchmarks [2], and in algebra/topology discharges [3, 4]. What unifies them is *packaging*: the same layered analysis applies when π, fibers, and sections are made mathematically explicit.

3 Exact scope

This summit paper is **not** a substitute for formal statements in Lean. It does not add new axioms. It does not assert that every formal system or every epistemic agent must exhibit non-exhaustion. It summarizes a research program whose precise carriers and hypotheses are documented in the repository and companion manuscripts.

4 Distinction from Gödel

Gödelian incompleteness exhibits *limits* of formal systems (undecidable sentences, non-recursive theories, etc.). The present program exhibits a *positive* stratification: where collapse occurs, where it does not, and how obstruction is organized. Route D aligns computability anchors with the classical story, but reflective non-exhaustion is not "Gödel's theorem in a new notation."

5 Not merely dependent-type proof relevance

Dependent type theory admits proof-relevant types; that observation alone is not the contribution. The contribution is a *theorem* about specific carriers in a machine-checked library: collapse at $\mathcal{B}_{\mathrm{can}}$, strict refinement of π_A, and fiber lemmas with the hypotheses used in development [1].

6 Why it matters across fields

Algebra: cocycle obstructions to splitting. Topology: contractible fibers in Quillen's hypotheses. Arithmetic: embedding problems as liftability. Verification: audit trails above bare certificates. The same architectural lens travels because the layers are mathematically standard once π and fibers are fixed.

7 Self-modeling, consciousness, and AGI (delimited)

Any analogy to self-modeling or subjective experience is **speculative** and *not* a theorem of this program. What *is* formalized are mathematical carriers and comparison maps in Lean. Philosophical reading is optional; the summit claim stands on the formal discharges and the validation survey.
